Field In A Theme

Carbon Fields allows you to define custom fields inside your theme if you have theme-specific fields that you do not intend to distribute separately:

1. Execute `git clone https://github.com/htmlburger/carbon-field-template.git --single-branch --depth 1 includes/my-field` in your theme dir
2. Delete the `includes/my-field/.git` directory
3. Add the following to your theme's composer.json:

```
"autoload": {
    "files": [
        "./includes/my-field/field.php"
    ],
    "psr-4": {
        "Carbon_Field_YOURFIELDNAME\\": "./includes/my-field/core/"
    }
}
```

4. Call `composer dumpautoload`
5. Browse to the `includes/my-field` directory
6. Call `npm install`
7. Edit `includes/my-field/webpack.config.js` and adjust the `const root` variable to point to the directory of Carbon Fields (e.g. `const root = path.resolve(__dirname, '../../vendor/htmlburger/carbon-fields');`)
8. Call `npm run build`
9. You now have a local custom field running from your theme
10. If the field is theme-specific and will not be distributed separately feel free to delete the `composer.json` and `composer.lock` files.
