Document: beforescriptexecute event

- Syntax
- Event type
- Examples
- Specifications
- Browser compatibility
- See also

The `beforescriptexecute` event fires when a static script is about to start executing. It does not fire if the element is added dynamically, such as with appendChild().

Syntax

Use the event name in addEventListener():

```
addEventListener("beforescriptexecute", (event) => { })
```

Alternatively, assign to the event handler property of the interface:

```
onbeforescriptexecute = (event) => { }
```

Event type

A generic Event.

Examples

```
function starting(e) {
  logMessage(`Starting script with ID: ${e.target.id}`);
}

document.addEventListener("beforescriptexecute", starting);
// Or (but note that this replaces other event listeners
// added using onbeforescriptexecute, if any)
document.onbeforescriptexecute = starting;
```
