Window: messageerror event

- Syntax
- Event type
- Examples
- Specifications
- Browser compatibility
- See also

The `messageerror` event is fired on a Window object when it receives a message that can't be deserialized.

This event is not cancellable and does not bubble.

Syntax

Use the event name in addEventListener():

```
addEventListener("messageerror", (event) => { })
```

Alternatively, assign to the event handler property of the interface:

```
onmessageerror = (event) => { }
```

Event type

A MessageEvent. Inherits from Event.

Examples

Listen for `messageerror` using addEventListener():

```
window.addEventListener("messageerror", (event) => {
  console.error(event);
});
```

The same, but using the `onmessageerror` event handler property (but note that this replaces other event listeners added using `onmessageerror`, if any):

```
window.onmessageerror = (event) => {
  console.error(event);
};
```

Specifications

Browser compatibility
