API Docs

- Adding/Removing Files
- Refreshing the Templated API Reference

This repo contains the source for documentation for the API on developer.wordpress.org (DevHub).

Adding/Removing Files

When creating new files, these must be added to the manifest. Run `bin/generate-manifest.php` to update this.

Removing files also requires regenerating the manifest. After deletion and sync with DevHub, the page also needs to be manually deleted from DevHub.

Refreshing the Templated API Reference

The reference section is created by parsing the output of a site's schema as retrieved from that site's REST API index route. The current method used to generate this approach is as follows:

- Create a local WordPress environment (always use the current or Release Candidate version of WordPress) using the local environment tool of your choice.
- Edit `/etc/hosts` to map the domain `example.com` to the IP of that WordPress instance, and ensure the site is configured to run at `example.com`.
- Run `composer install` in this project's root directory to install dependencies.
- Run `composer run-script regenerate` in this project's root directory to run the asset regeneration script.
- Use `git status` and `git diff` to validate that the files were updated as expected.
